

OAXACAN SWALLOWTAIL (*Papilio esperanza*)

Status

The Oaxacan swallowtail is one of Mexico's rarest butterflies. This swallowtail is listed as Vulnerable by the IUCN because of its severely restricted range.

Description

This medium sized, black, yellow and orange swallowtail was first described in 1975.

Natural history

Little is known about the life history of this butterfly.

Distribution

The Oaxacan swallowtail is only found in only one small area in the montane cloud forests in northern Oaxaca, between 1400 and 2500 meters above sea level.

Threats

This species is at risk because of its very limited geographic range and potential destruction of its limited cloud forest habitat. However, the biggest current threat is over collection. The best known site, which happens to be close to a road, has seen a decrease in population because of poaching (according to Tyler, et al., 1994 – see references below).

Conservation

Inclusion of this species on the Federal Endangered Species List would regulate its transport into the U.S. and thus help reduce the market for pinned specimens.
